## SUPPLEMENT TO BAYESIAN AND FREQUENTIST INFERENCE IN PARTIALLY IDENTIFIED MODELS

(Econometrica, Vol. 80, No. 2, March 2012, 755-782)

## By Hyungsik Roger Moon and Frank Schorfheide

THIS SUPPLEMENT contains proofs and derivations for results presented in the main paper. The notation used in the supplement is defined in the main paper.

## A. PROOFS

This section contains proofs for Theorems 1(ii) and 2 as well as Corollary 1. The proof of Theorem 1 requires Lemma A.1, which is stated below.

Proof of Theorem 1(ii): Since the $L_{1}$ distance satisfies the triangle inequality

$$
\left\|P_{Y^{n}}^{\theta}-P_{\hat{\phi}_{n}}^{\theta}\right\| \leq\left\|P_{Y^{n}}^{\theta}-P_{N, Y^{n}}^{\theta}\right\|+\left\|P_{N, Y^{n}}^{\theta}-P_{\hat{\phi}_{n}}^{\theta}\right\|,
$$

it suffices to show that $\left\|P_{N, Y^{n}}^{\theta}-P_{\hat{\phi}_{n}}^{\theta}\right\| \xrightarrow{\mathbb{P}} 0$ :

$$
\begin{aligned}
&\left\|P_{N, Y^{n}}^{\theta}-P_{\hat{\phi}_{n}}^{\theta}\right\| \\
& \leq \int_{\mathbb{R}^{m}}\left\|P_{\hat{\phi}_{n}+\hat{J}_{n}^{-1 / 2} D_{n}^{-1} s}^{\theta}-P_{\hat{\phi}_{n}}^{\theta}\right\| d N(0, I)(s) \\
& \leq \int_{\mathbb{R}^{m}} I\left\{\left\|\hat{\phi}_{n}-\phi_{0}\right\|<\delta\right\} I\left\{\left\|\hat{\phi}_{n}-\phi_{0}+\hat{J}_{n}^{-1 / 2} D_{n}^{-1} s\right\|<\delta\right\} \\
& \times\left\|P_{\hat{\phi}_{n}+\hat{J}_{n}^{-1 / 2} D_{n}^{-1} s}^{\theta}-P_{\hat{\phi}_{n}}^{\theta}\right\| d N(0, I)(s)+2 I\left\{\left\|\hat{\phi}_{n}-\phi_{0}\right\| \geq \delta\right\} \\
&+2 \int_{\mathbb{R}^{m}} I\left\{\left\|\hat{\phi}_{n}-\phi_{0}+\hat{J}_{n}^{-1 / 2} D_{n}^{-1} s\right\| \geq \delta\right\} d N(0, I)(s) \\
& \leq \int_{\mathbb{R}^{m}} M\left(\phi_{0}, \delta\right)\left\|\hat{J}_{n}^{-1 / 2} D_{n}^{-1} s\right\| d N(0, I)(s)+2 I\left\{\left\|\hat{\phi}_{n}-\phi_{0}\right\| \geq \delta\right\} \\
&+2 I\left\{\left\|\hat{\phi}_{n}-\phi_{0}\right\| \geq \delta / 2\right\} \\
&+2 \int_{\mathbb{R}^{m}} I\left\{\left\|\hat{J}_{n}^{-1 / 2} D_{n}^{-1} s\right\| \geq \delta / 2\right\} d N(0, I)(s) \\
& \leq M\left(\phi_{0}, \delta\right)\left\|\hat{J}_{n}^{-1 / 2}\right\|\left\|D_{n}^{-1}\right\| \int_{\mathbb{R}^{m}}\|s\| d N(0, I)(s)+o_{p}(1) \xrightarrow{\mathbb{P}} 0 .
\end{aligned}
$$

For the second inequality, we bound the $L_{1}$ distance $\left\|P_{\hat{\phi}_{n}+\hat{J}_{n}^{-1 / 2} D_{n}^{-1} s}^{\theta}-P_{\hat{\phi}_{n}}^{\theta}\right\|$ by 2 if either $\hat{\phi}_{n}$ or $\hat{\phi}_{n}+\hat{J}_{n}^{-1 / 2} D_{n}^{-1} s$ lies outside of the $N_{\delta}\left(\phi_{0}\right)$ neighborhood. For
the third inequality, we use the Lipschitz bound of Assumption 2 and the inequality $I\{\|x+y\| \geq \delta\} \leq I\{\|x\| \geq \delta / 2\}+I\{\|y\| \geq \delta / 2\}$. The last line follows from Assumption 1 that $\hat{\phi}_{n}$ converges in probability to $\phi_{0},\left\|D_{n}\right\| \uparrow \infty$, and $\hat{J}_{n}^{-1 / 2}=O_{p}(1)$. A similar argument can be used to establish the convergence of $P_{Y^{n}}^{\theta}$ to $P_{\phi_{0}}^{\theta}$.
Q.E.D.

The following lemma is needed for the subsequent proof of Theorem 2. To simplify the notation, let $p_{Y}(\theta)=p\left(\theta \mid Y^{n}\right)$ and $p_{0}(\theta)=p\left(\theta \mid \phi_{0}\right)$. Similarly, we abbreviate the thresholds $\kappa_{Y^{n}}$ and $\kappa_{\phi_{0}}$ by $\kappa_{Y}$ and $\kappa_{0}$.

Lemma A.1: Suppose that $\int\left|p_{Y}(\theta)-p_{0}(\theta)\right| d \theta=o_{p}(1)$ and $\int I\left\{p_{0}(\theta)=\right.$ $\left.\kappa_{0}\right\} p_{0}(\theta) d \theta=0$, where $\kappa_{0}<\infty$. Then

$$
\int\left|I\left\{p_{Y}(\theta) \geq \kappa_{0}\right\}-I\left\{p_{0}(\theta) \geq \kappa_{0}\right\}\right| p_{Y}(\theta) d \theta=o_{p}(1)
$$

Proof: This lemma is used to prove Theorem 2. Write

$$
\begin{aligned}
& \int\left|I\left\{p_{Y}(\theta) \geq \kappa_{0}\right\}-I\left\{p_{0}(\theta) \geq \kappa_{0}\right\}\right| p_{Y}(\theta) d \theta \\
& =\int I\left\{\theta \mid p_{Y}(\theta) \geq \kappa_{0}, p_{0}(\theta)<\kappa_{0}\right\} p_{Y}(\theta) d \theta \\
& \quad+\int I\left\{\theta \mid p_{Y}(\theta)<\kappa_{0}, p_{0}(\theta) \geq \kappa_{0}\right\} p_{Y}(\theta) d \theta \\
& =\int_{\theta \in A_{n}} p_{Y}(\theta) d \theta+\int_{\theta \in B_{n}} p_{Y}(\theta) d \theta=(\mathrm{I})+(\mathrm{II}),
\end{aligned}
$$

say. We subsequently construct $o_{p}$ (1) bounds for terms (I) and (II).
Bound for (I): We deduce from the $L_{1}$ convergence assumption of $p_{Y}(\theta)$ to $p_{0}(\theta)$ that

$$
(\mathrm{I})=\int_{\theta \in A_{n}} p_{Y}(\theta) d \theta=\int_{\theta \in A_{n}} p_{0}(\theta) d \theta+o_{p}(1)=(\mathrm{Ia})+o_{p}(1) .
$$

Thus, it suffices to construct an $o_{p}(1)$ bound for (Ia). Define the function

$$
f_{n}(\theta)=p_{Y}(\theta)-p_{0}(\theta)
$$

and notice that $f_{n}(\theta)>0$ for $\theta \in A_{n}$. With this definition,

$$
\begin{align*}
\int_{A_{n}} f_{n}(\theta) p_{0}(\theta) d \theta & =\int_{A_{n}}\left|p_{Y}(\theta)-p_{0}(\theta)\right| p_{0}(\theta) d \theta  \tag{A.1}\\
& \leq \kappa_{0} \int_{A_{n}}\left|p_{Y}(\theta)-p_{0}(\theta)\right| d \theta=o_{p}(1)
\end{align*}
$$

The inequality follows from $p_{0}(\theta)<\kappa_{0}$ on the set $A_{n}$. The $o_{p}(1)$ statement is a consequence of the assumptions that $p_{Y}(\theta)$ converges to $p_{0}(\theta)$ in $L_{1}$ and that $\kappa_{0}$ is finite.

Now notice that
(A.2) $I\left\{\theta \in A_{n}\right\}=I\left\{I\left\{\theta \in A_{n}\right\} f_{n}(\theta)>0\right\}$.

If $\theta \in A_{n}$, then $f_{n}(\theta)>0$, which means that $I\left\{\theta \in A_{n}\right\} f_{n}(\theta)>0$. Moreover, for any $\eta>0$, we obtain the inequality
(A.3) $I\left\{I\left\{\theta \in A_{n}\right\} f_{n}(\theta)>\eta\right\} \leq \frac{1}{\eta} I\left\{\theta \in A_{n}\right\} f_{n}(\theta)$.

Thus,

$$
\begin{aligned}
(\mathrm{Ia})= & \int I\left\{I\left\{\theta \in A_{n}\right\} f_{n}(\theta)>0\right\} p_{0}(\theta) d \theta \\
\leq & \int I\left\{I\left\{\theta \in A_{n}\right\} f_{n}(\theta)>0\right\} p_{0}(\theta) d \theta \\
& -\int I\left\{I\left\{\theta \in A_{n}\right\} f_{n}(\theta)>\eta\right\} p_{0}(\theta) d \theta+\frac{1}{\eta} \int_{A_{n}} f_{n}(\theta) p_{0}(\theta) d \theta \\
= & \int I\left\{0<I\left\{\theta \in A_{n}\right\} f_{n}(\theta) \leq \eta\right\} p_{0}(\theta) d \theta+\frac{1}{\eta} \int_{A_{n}} f_{n}(\theta) p_{0}(\theta) d \theta \\
= & (\mathrm{Ib})+(\mathrm{Ic})
\end{aligned}
$$

say. The first equality follows from (A.2). The inequality is a consequence of (A.3).

To bound (Ib) notice that

$$
I\left\{0<I\left\{\theta \in A_{n}\right\} f_{n}(\theta) \leq \eta\right\} \leq I\left\{\kappa_{0}-\eta \leq p_{0}(\theta) \leq \kappa_{0}+\eta\right\}
$$

For the indicator function on the left-hand side to be 1 , it has to be the case that $\theta \in A_{n}$ and $f_{n}(\theta) \leq \eta$. On the set $A_{n}, p_{Y}(\theta) \geq \kappa_{0}$, which leads to

$$
\kappa_{0} \leq p_{Y}(\theta)=p_{0}(\theta)+f_{n}(\theta) \leq p_{0}(\theta)+\eta
$$

that is,

$$
\kappa_{0}-\eta \leq p_{0}(\theta)
$$

Moreover, $p_{0}(\theta)<\kappa_{0} \leq \kappa_{0}+\eta$ and, therefore, the following inequality is satisfied:

$$
\kappa_{0}-\eta \leq p_{0}(\theta) \leq \kappa_{0}+\eta
$$

Thus,

$$
(\mathrm{Ib}) \leq \int I\left\{\kappa_{0}-\eta \leq p_{0}(\theta) \leq \kappa_{0}+\eta\right\} p_{0}(\theta) d \theta
$$

Based on the dominated convergence theorem and the assumption $\int I\left\{p_{0}(\theta)=\right.$ $\left.\kappa_{0}\right\} p_{0}(\theta)=0$, we deduce that
(A.4) $\lim _{\eta \rightarrow 0} \int I\left\{\kappa_{0}-\eta \leq p_{0}(\theta) \leq \kappa_{0}+\eta\right\} p_{0}(\theta) d \theta$ $=\int I\left\{p_{0}(\theta)=\kappa_{0}\right\} p_{0}(\theta)=0$.

Notice that our bound for (Ib) is deterministic.
To establish that (Ia) $\xrightarrow{\mathbb{P}} 0$, it suffices to show that for every $\varepsilon>0$ and $\delta>0$, there exists an $N(\varepsilon, \delta)$ such that for $n \geq N(\varepsilon, \delta)$,

$$
\mathbb{P}\{(\mathrm{Ia})>\varepsilon\} \leq \mathbb{P}\{(\mathrm{Ib})>\varepsilon / 2\}+\mathbb{P}\{(\mathrm{Ic})>\varepsilon / 2\}<\delta .
$$

Based on (A.4), we can find an $\eta(\varepsilon)>0$ such that $\mathbb{P}\{(\mathrm{Ib})>\varepsilon / 2\}=0$. To obtain a bound for (Ic), define $Z_{n}=\int_{A_{n}} f_{n}(\theta) p_{0}(\theta) d \theta$ such that (Ic) $=Z_{n} / \eta$. According to (A.1), $Z_{n}=o_{p}(1)$. Thus, we can find an $N(\varepsilon, \delta)$ such that

$$
\mathbb{P}\left\{\left|Z_{n}\right|>\eta(\varepsilon) \frac{\varepsilon}{2}\right\}<\delta
$$

whenever $n \geq N(\varepsilon, \delta)$, which shows that (Ia) $=o_{p}(1)$.
Bound for (II): This bound can be obtained following the same steps. Change the definition of $f_{n}(\theta)$ to

$$
f_{n}(\theta)=p_{0}(\theta)-p_{Y}(\theta)
$$

Using this definition, we obtain that

$$
\begin{aligned}
\int_{\theta \in B_{n}} f_{n}(\theta) p_{Y}(\theta) d \theta & =\int_{\theta \in B_{n}}\left(p_{0}(\theta)-p_{Y}(\theta)\right) p_{Y}(\theta) d \theta \\
& \leq \kappa_{0} \int_{\theta \in B_{n}}\left|p_{0}(\theta)-p_{Y}(\theta)\right| d \theta=o_{p}(1)
\end{aligned}
$$

because on the set $B_{n}$, the density $p_{Y}(\theta)$ is bounded by $\kappa_{0}$. Now consider

$$
\begin{aligned}
(\mathrm{II}) & =\int_{B_{n}} p_{Y}(\theta) d \theta \\
& =\int I\left\{I\left\{\theta \in B_{n}\right\} f_{n}(\theta)>0\right\} p_{Y}(\theta) d \theta
\end{aligned}
$$

$$
\begin{aligned}
\leq & \int I\left\{I\left\{\theta \in B_{n}\right\} f_{n}(\theta)>0\right\} p_{Y}(\theta) d \theta \\
& -\int I\left\{I\left\{\theta \in B_{n}\right\} f_{n}(\theta)>\eta\right\} p_{Y}(\theta) d \theta \\
& +\frac{1}{\eta} \int_{B_{n}} f_{n}(\theta) p_{Y}(\theta) d \theta \\
= & \int I\left\{0<I\left\{\theta \in B_{n}\right\} f_{n}(\theta) \leq \eta\right\} p_{0}(\theta) d \theta \\
& +\frac{1}{\eta} \int_{B_{n}} f_{n}(\theta) p_{Y}(\theta) d \theta+o_{p}(1) \\
= & (\mathrm{IIb})+(\mathrm{IIc})+o_{p}(1)
\end{aligned}
$$

In the last line, we used the $L_{1}$ convergence to replace $p_{Y}(\theta)$ by $p_{0}(\theta)$ in the definition of term (IIb) which introduces an additional $o_{p}(1)$ term.

To bound (IIb) notice that

$$
I\left\{0<I\left\{\theta \in B_{n}\right\} f_{n}(\theta) \leq \eta\right\} \leq I\left\{\kappa_{0}-\eta \leq p_{n}(\theta) \leq \kappa_{0}+\eta\right\}
$$

For the indicator function on the left-hand side to be 1 , it has to be the case that $\theta \in B_{n}$ and $f_{n}(\theta) \leq \eta$. On the set $B_{n}, p_{Y}(\theta)<\kappa_{0}$, which leads to

$$
\kappa_{0}>p_{Y}(\theta)=p_{0}(\theta)-f_{n}(\theta) \geq p_{0}(\theta)-\eta,
$$

that is,

$$
\kappa_{0}+\eta \geq p_{0}(\theta)
$$

Moreover, $p_{0}(\theta) \geq \kappa_{0} \geq \kappa_{0}-\eta$ and, therefore, the following inequality is satisfied:

$$
\kappa_{0}-\eta \leq p_{0}(\theta) \leq \kappa_{0}+\eta
$$

Thus,

$$
(\mathrm{IIb}) \leq \int I\left\{\kappa_{0} \leq p_{0}(\theta)<\kappa_{0}+\eta\right\} p_{0}(\theta) d \theta
$$

Dominated convergence implies that the bound converges to 0 as $\eta \longrightarrow 0$. The remaining steps needed to establish that (II) $=o_{p}(1)$ are identical to the steps followed for term (I).
Q.E.D.

Proof of Theorem 2: Throughout the proof, we express the symmetric difference between two sets in terms of indicator functions: $A \ominus B=\mid I\{x \in$ $A\}-I\{x \in B\} \mid$.

Part (i). To simplify the notation let $p_{Y}(\theta)=p\left(\theta \mid Y^{n}\right)$ and $p_{0}(\theta)=p\left(\theta \mid \phi_{0}\right)$. Similarly, we abbreviate the thresholds $\kappa_{Y^{n}}$ and $\kappa_{\phi_{0}}$ by $\kappa_{Y}$ and $\kappa_{0}$. Write

$$
\begin{aligned}
& \int \quad\left|I\left\{p_{Y}(\theta) \geq \kappa_{Y}\right\}-I\left\{p_{0}(\theta) \geq \kappa_{0}\right\}\right| p_{Y}(\theta) d \theta \\
& =\int\left|I\left\{p_{Y}(\theta) \geq \kappa_{Y}\right\}-I\left\{p_{Y}(\theta) \geq \kappa_{0}\right\}\right| p_{Y}(\theta) d \theta \\
& \quad+\int\left|I\left\{p_{Y}(\theta) \geq \kappa_{0}\right\}-I\left\{p_{0}(\theta) \geq \kappa_{0}\right\}\right| p_{Y}(\theta) d \theta \\
& = \\
& \quad(\mathrm{I})+(\mathrm{II}),
\end{aligned}
$$

say. In view of our assumptions, Lemma A. 1 provides an $o_{p}(1)$ bound for term (II). Now consider term (I). Since, by construction,

$$
\int I\left\{p_{Y}(\theta) \geq \kappa_{Y}\right\} p_{Y}(\theta) d \theta=1-\tau
$$

we can write term (I) as

$$
\begin{aligned}
(\mathrm{I})= & \int I\left\{p_{Y}(\theta) \geq \min \left\{\kappa_{0}, \kappa_{Y}\right\}\right\} p_{Y}(\theta) d \theta \\
& -\int I\left\{p_{Y}(\theta) \geq \max \left\{\kappa_{0}, \kappa_{Y}\right\}\right\} p_{Y}(\theta) d \theta \\
= & I\left\{\kappa_{0} \geq \kappa_{Y}\right\}\left[(1-\tau)-\int I\left\{p_{Y}(\theta) \geq \kappa_{0}\right\} p_{Y}(\theta) d \theta\right] \\
& +I\left\{\kappa_{0}<\kappa_{Y}\right\}\left[\int I\left\{p_{Y}(\theta) \geq \kappa_{0}\right\} p_{Y}(\theta) d \theta-(1-\tau)\right] \\
= & \left|\int I\left\{p_{Y}(\theta) \geq \kappa_{0}\right\} p_{Y}(\theta) d \theta-(1-\tau)\right|
\end{aligned}
$$

To show that $I=o_{p}(1)$, we add and subtract $\int I\left\{p_{0}(\theta) \geq \kappa_{0}\right\} p_{Y}(\theta) d \theta$ and, using the triangle inequality,

$$
\begin{aligned}
(\mathrm{I}) \leq & \left|\int I\left\{p_{Y}(\theta) \geq \kappa_{0}\right\} p_{Y}(\theta) d \theta-\int I\left\{p_{0}(\theta) \geq \kappa_{0}\right\} p_{Y}(\theta) d \theta\right| \\
& +\left|\int I\left\{p_{0}(\theta) \geq \kappa_{0}\right\} p_{Y}(\theta) d \theta-(1-\tau)\right| \\
= & \left|\int I\left\{p_{Y}(\theta) \geq \kappa_{0}\right\} p_{Y}(\theta) d \theta-\int I\left\{p_{0}(\theta) \geq \kappa_{0}\right\} p_{Y}(\theta) d \theta\right|
\end{aligned}
$$

$$
\begin{aligned}
& +\left|\int I\left\{p_{0}(\theta) \geq \kappa_{0}\right\} p_{Y}(\theta) d \theta-\int I\left\{p_{0}(\theta) \geq \kappa_{0}\right\} p_{0}(\theta) d \theta\right| \\
\leq & \int\left|I\left\{p_{Y}(\theta) \geq \kappa_{0}\right\}-I\left\{p_{0}(\theta) \geq \kappa_{0}\right\}\right| p_{Y}(\theta) d \theta \\
& +\int I\left\{p_{0}(\theta) \geq \kappa_{0}\right\}\left|p_{Y}(\theta)-p_{0}(\theta)\right| d \theta=o_{p}(1)
\end{aligned}
$$

The first equality holds because $\int I\left\{p_{0}(\theta) \geq \kappa_{0}\right\} p_{0}(\theta) d \theta=1-\tau$. The final $o_{p}(1)$ result follows from Lemma A. 1 and the $L_{1}$ convergence of the posterior densities established in Theorem 1.

Part (ii). The triangle inequality implies that

$$
\left\|P_{\hat{\phi}_{n}}^{\theta}-P_{\phi_{0}}^{\theta}\right\| \leq\left\|P_{Y^{n}}^{\theta}-P_{\hat{\phi}_{n}}^{\theta}\right\|+\left\|P_{Y^{n}}^{\theta}-P_{\phi_{0}}^{\theta}\right\| \xrightarrow{\mathbb{P}} 0
$$

by Theorem 1(ii). Let $p_{n}(\theta)=p\left(\theta \mid \hat{\phi}_{n}\right)$ and $\kappa_{n}=\kappa_{\hat{\phi}_{n}}$. Then using the same argument as for part (i), replacing $p_{Y}(\theta)$ by $p_{n}(\theta)$ and $\kappa_{Y}$ by $\kappa_{n}$, we can easily establish that

$$
\begin{equation*}
\int\left|I\left\{\theta \in \mathrm{CS}_{\mathrm{HPD}}^{\theta}\left(\hat{\phi}_{n}\right)\right\}-I\left\{\theta \in \mathrm{CS}_{\mathrm{HPD}}^{\theta}\left(\phi_{0}\right)\right\}\right| d P_{Y^{n}}^{\theta} \xrightarrow{\mathbb{P}} 0 . \tag{A.5}
\end{equation*}
$$

Now consider the inequality

$$
\begin{align*}
& |I\{\theta \in A\}-I\{\theta \in B\}|  \tag{A.6}\\
& \quad \leq|I\{\theta \in A\}-I\{\theta \in C\}|+|I\{\theta \in B\}-I\{\theta \in C\}| \\
& \quad=(\mathrm{I})+(\mathrm{II})
\end{align*}
$$

If the left-hand side of (A.6) is 0 , then the inequality is trivially satisfied. The left-hand side of (A.6) is 1 if $\theta \in A$ and $\theta \notin B$ or if $\theta \notin A$ and $\theta \in B$. Since the statement of the inequality is symmetric in $A$ and $B$, we focus on the first case. If $\theta \in A, \theta \notin B$, and $\theta \in C$, then (I) $=|1-1|=0$ and (II) $=|0-1|=1$. If $\theta \in A$, $\theta \notin B$, and $\theta \notin C$, then (I) $=|1-0|=1$ and (II) $=|0+0|=0$. We deduce that whenever the left-hand side of (A.6) is equal to 1 , the right-hand side is equal to 1 as well, which confirms the inequality.

Now let

$$
A=\mathrm{CS}_{\mathrm{HPD}}^{\theta}\left(Y^{n}\right), \quad B=\mathrm{CS}_{\mathrm{HPD}}^{\theta}\left(\hat{\phi}_{n}\right), \quad \text { and } \quad C=\mathrm{CS}_{\mathrm{HPD}}^{\theta}\left(\phi_{0}\right) .
$$

Integrating both sides of (A.6) yields

$$
\begin{aligned}
& \int|I\{\theta \in A\}-I\{\theta \in B\}| p_{Y}(\theta) d \theta \\
& \quad \leq \int|I\{\theta \in A\}-I\{\theta \in C\}| p_{Y}(\theta) d \theta
\end{aligned}
$$

$$
\begin{aligned}
& +\int|I\{\theta \in B\}-I\{\theta \in C\}| p_{Y}(\theta) d \theta \\
= & o_{p}(1)
\end{aligned}
$$

The $o_{p}(1)$ statement follows from part (i) and (A.5).
Q.E.D.

Proof of Corollary 1: Recall that $\Theta\left(\hat{\phi}_{n}\right) \subset \mathrm{CS}_{F}^{\theta}\left(Y^{n}\right)$ and $\mathrm{CS}_{\mathrm{HPD}}^{\theta}\left(Y^{n}\right) \subset$ $\Theta$. Part (i) follows from the inequalities

$$
\begin{aligned}
& P_{Y^{n}}^{\theta}\left(\mathrm{CS}_{\mathrm{HPD}}^{\theta}\left(Y^{n}\right) \backslash \mathrm{CS}_{F}^{\theta}\left(Y^{n}\right)\right) \\
& \quad \leq P_{Y^{n}}^{\theta}\left(\Theta \backslash \Theta\left(\hat{\phi}_{n}\right)\right) \\
& \quad=1-P_{Y^{n}}^{\theta}\left(\Theta\left(\hat{\phi}_{n}\right)\right) \\
& \quad \leq 1-P_{\hat{\phi}_{n}}^{\theta}\left(\Theta\left(\hat{\phi}_{n}\right)\right)+\left|P_{\hat{\phi}_{n}}^{\theta}\left(\Theta\left(\hat{\phi}_{n}\right)\right)-P_{Y^{n}}^{\theta}\left(\Theta\left(\hat{\phi}_{n}\right)\right)\right| \\
& \quad \xrightarrow{\mathbb{P}} 0 .
\end{aligned}
$$

The probability limit is obtained from $P_{\hat{\phi}_{n}}^{\theta}\left(\Theta\left(\hat{\phi}_{n}\right)\right)=1$ and Theorem 1(ii).
Part (ii) can be deduced from the inequalities

$$
\begin{aligned}
& P_{Y^{n}}^{\theta}\left(\mathrm{CS}_{F}^{\theta}\left(Y^{n}\right) \backslash \mathrm{CS}_{\mathrm{HPD}}^{\theta}\left(Y^{n}\right)\right) \\
& \quad \geq P_{Y^{n}}^{\theta}\left(\Theta\left(\hat{\phi}_{n}\right) \backslash \mathrm{CS}_{\mathrm{HPD}}^{\theta}\left(Y^{n}\right)\right) \\
& \quad \geq P_{Y^{n}}^{\theta}\left(\Theta\left(\hat{\phi}_{n}\right)\right)-P_{Y^{n}}^{\theta}\left(\mathrm{CS}_{\mathrm{HPD}}^{\theta}\left(Y^{n}\right)\right) \\
& \quad \geq P_{\hat{\phi}_{n}}^{\theta}\left(\Theta\left(\hat{\phi}_{n}\right)\right)-P_{Y^{n}}^{\theta}\left(\mathrm{CS}_{\mathrm{HPD}}^{\theta}\left(Y^{n}\right)\right)-\left|P_{Y^{n}}^{\theta}\left(\Theta\left(\hat{\phi}_{n}\right)\right)-P_{\hat{\phi}_{n}}^{\theta}\left(\Theta\left(\hat{\phi}_{n}\right)\right)\right| \\
& \quad \xrightarrow{\mathbb{P}} 1-(1-\tau)=\tau .
\end{aligned}
$$

The probability limit is obtained from $P_{\hat{\phi}_{n}}^{\theta}\left(\Theta\left(\hat{\phi}_{n}\right)\right)=1, P_{Y^{n}}^{\theta}\left(\mathrm{CS}_{\mathrm{HPD}}^{\theta}\left(Y^{n}\right)\right)=1-$ $\tau$, and Theorem 1(ii).
Q.E.D.

## B. DERIVATIONS OF RESULTS

This section contains derivations for Section 2 and for Remark 2 in Section 3, as well as detailed derivations for the entry game illustration in Section 4.

## Derivations for Section 2

Direct calculation of the posterior density of $\theta$ :

$$
p\left(\theta \mid Y^{n}\right)=\frac{1}{\sqrt{2 \pi / n}} \int_{-\infty}^{\infty} \frac{1}{\lambda} I\{\phi \leq \theta \leq \phi+\lambda\} \exp \left\{-\frac{n}{2}\left(\phi-\hat{\phi}_{n}\right)^{2}\right\} d \phi
$$

$$
\begin{aligned}
& =\frac{1}{\lambda} \frac{1}{\sqrt{2 \pi}} \int_{\sqrt{n}\left(\theta-\hat{\phi}_{n}-\lambda\right)}^{\sqrt{n}\left(\theta-\hat{\phi}_{n}\right)} \exp \left\{-\frac{s^{2}}{2}\right\} d s \\
& =\frac{1}{\lambda}\left[\Phi_{N}\left(\sqrt{n}\left(\theta-\hat{\phi}_{n}\right)\right)-\Phi_{N}\left(\sqrt{n}\left(\theta-\hat{\phi}_{n}-\lambda\right)\right)\right]
\end{aligned}
$$

The second equality follows from rearranging the inequalities in the indicator function and the change of variables $s=\sqrt{n}\left(\phi-\hat{\phi}_{n}\right)$. It is straightforward to verify that $p\left(\theta \mid Y^{n}\right)$ has a single mode at $\theta=\hat{\phi}_{n}+\lambda / 2$ and is symmetric around the mode.

## Derivations for Section 3

Direct Calculations to Verify Equation (18): We begin with the change of variable $s=\hat{J}_{n}^{1 / 2} D_{n}\left(\theta-\hat{\phi}_{n}+\tilde{s}\right)$, which leads to

$$
\begin{aligned}
p\left(\theta \mid Y^{n}\right) & =p_{N}\left(\theta \mid Y^{n}\right) \\
& =\frac{1}{\lambda_{n}} \int f\left(\frac{\theta-\hat{\phi}_{n}-\hat{J}_{n}^{-1 / 2} D_{n}^{-1} s}{\lambda_{n}}\right) \varphi_{N}(s) d s \\
& =\frac{1}{\lambda_{n}}\left|\hat{J}_{n}^{1 / 2} D_{n}\right| \int_{\tilde{s}=-\lambda_{n}}^{0} f\left(-\lambda_{n}^{-1} \tilde{s}\right) \varphi_{N}\left(\hat{J}_{n}^{1 / 2} D_{n}\left(\theta-\hat{\phi}_{n}+\tilde{s}\right)\right) d \tilde{s} .
\end{aligned}
$$

The second equality makes use of the assumption that $f(x)=0$ outside of the unit interval. The $L_{1}$ distance can be bounded as

$$
\begin{align*}
& \int_{\theta}\left|p_{N}\left(\theta \mid Y^{n}\right)-\left|\hat{J}_{n}^{1 / 2} D_{n}\right| \varphi_{N}\left(\hat{J}_{n}^{1 / 2} D_{n}\left(\theta-\hat{\phi}_{n}\right)\right)\right| d \theta  \tag{B.1}\\
& =\left|\hat{J}_{n}^{1 / 2} D_{n}\right| \int_{\theta} \left\lvert\, \int_{\tilde{s}=-\lambda_{n}}^{0} \frac{1}{\lambda_{n}} f\left(-\lambda_{n}^{-1} \tilde{s}\right)\right. \\
& \quad \times\left[\varphi_{N}\left(\hat{J}_{n}^{1 / 2} D_{n}\left(\theta-\hat{\phi}_{n}+\tilde{s}\right)\right)-\varphi_{N}\left(\hat{J}_{n}^{1 / 2} D_{n}\left(\theta-\hat{\phi}_{n}\right)\right)\right] d \tilde{s} \mid d \theta \\
& \leq\left|\hat{J}_{n}^{1 / 2} D_{n}\right| \int_{\tilde{s}=-\lambda_{n}}^{0} \int_{\theta} \frac{1}{\lambda_{n}} f\left(-\lambda_{n}^{-1} \tilde{s}\right) \\
& \quad \times\left|\varphi_{N}\left(\hat{J}_{n}^{1 / 2} D_{n}\left(\theta-\hat{\phi}_{n}+\tilde{s}\right)\right)-\varphi_{N}\left(\hat{J}_{n}^{1 / 2} D_{n}\left(\theta-\hat{\phi}_{n}\right)\right)\right| d \theta d \tilde{s} \\
& \leq \\
& \leq \int_{\tilde{s}=-\lambda_{n}}^{0} \frac{1}{\lambda_{n}} f\left(-\lambda_{n}^{-1} \tilde{s}\right) \int_{\tilde{\theta}}\left|\varphi_{N}\left(\tilde{\theta}+\hat{J}_{n}^{1 / 2} D_{n} \tilde{s}\right)-\varphi_{N}(\tilde{\theta})\right| d \tilde{\theta} d \tilde{s} .
\end{align*}
$$

The first equality follows because $\int_{0}^{1} f(x) d x=1$ and $\varphi_{N}\left(\hat{J}_{n}^{1 / 2} D_{n}\left(\theta-\hat{\phi}_{n}\right)\right)$ does not depend on $\tilde{s}$. The last inequality is based on the change of variables $\tilde{\theta}=$ $\hat{J}_{n}^{1 / 2} D_{n}\left(\theta-\hat{\phi}_{n}\right)$.

Now consider the difference $\varphi_{N}(\tilde{\theta}+h)-\varphi_{N}(\tilde{\theta})$ for $-\bar{h} \leq h \leq 0$. By direct calculation, we obtain

$$
\begin{aligned}
\left|\varphi_{N}(\tilde{\theta}+h)-\varphi_{N}(\tilde{\theta})\right| & =\left|(2 \pi)^{-1 / 2} \exp \left\{-\frac{1}{2}(\tilde{\theta}+h)^{2}\right\}-\varphi_{N}(\tilde{\theta})\right| \\
& =\left|\exp \left\{-\frac{1}{2}\left(2 \tilde{\theta} h+h^{2}\right)\right\}-1\right| \varphi_{N}(\tilde{\theta})
\end{aligned}
$$

A first-order Taylor series expansion around $h=0$ yields

$$
\begin{aligned}
& \exp \left\{-\frac{1}{2}\left(2 \tilde{\theta} h+h^{2}\right)\right\}-1 \\
& \quad=-\left(\tilde{\theta}+h_{*}(\tilde{\theta})\right) \exp \left\{-\tilde{\theta} h_{*}(\tilde{\theta})\right\} \exp \left\{-h_{*}^{2}(\tilde{\theta}) / 2\right\} h
\end{aligned}
$$

where $-\bar{h} \leq h_{*}(\tilde{\theta}) \leq 0$. Thus, on the interval $-\bar{h} \leq h \leq 0$, we obtain the bound

$$
\begin{align*}
& \left|\exp \left\{-\frac{1}{2}\left(2 \tilde{\theta} h+h^{2}\right)\right\}-1\right| \varphi_{N}(\tilde{\theta})  \tag{B.2}\\
& \quad \leq(|\tilde{\theta}|+\bar{h}) \exp \{-\tilde{\theta} \bar{h} I\{\tilde{\theta} \leq 0\}\} \bar{h} \varphi_{N}(\tilde{\theta})
\end{align*}
$$

Replacing $\bar{h}$ by $\hat{J}_{n}^{1 / 2} D_{n} \lambda_{n}$ in (B.2) and combining (B.1) with (B.2) leads to

$$
\begin{aligned}
& \int_{\theta}\left|p_{N}\left(\theta \mid Y^{n}\right)-\left|\hat{J}_{n}^{1 / 2} D_{n}\right| \varphi_{N}\left(\hat{J}_{n}^{1 / 2} D_{n}\left(\theta-\hat{\phi}_{n}\right)\right)\right| d \theta \\
& \leq \hat{J}_{n}^{1 / 2} D_{n} \lambda_{n} \int_{\tilde{\theta}}\left(|\tilde{\theta}|+\hat{J}_{n}^{1 / 2} D_{n} \lambda_{n}\right) \\
& \quad \times \exp \left\{-\tilde{\theta} \hat{J}_{n}^{1 / 2} D_{n} \lambda_{n} I\{\tilde{\theta} \leq 0\}\right\} \varphi_{N}(\tilde{\theta}) d \tilde{\theta} \\
& =o_{p}(1)
\end{aligned}
$$

The $o_{p}(1)$ statement follows because $D_{n} \lambda_{n} \longrightarrow 0$, and we can find a finite constant $M$ and an $N_{M}$ such that for $n>N_{M}$,

$$
\int_{\tilde{\theta}}\left(|\tilde{\theta}|+\hat{J}_{n}^{1 / 2} D_{n} \lambda_{n}\right) \exp \left\{-\tilde{\theta} \hat{J}_{n}^{1 / 2} D_{n} \lambda_{n} I\{\tilde{\theta} \leq 0\}\right\} \varphi_{N}(\tilde{\theta}) d \tilde{\theta} \leq M
$$

with probability approaching 1.

## Derivations for Section 4

The probabilities that firm $i$ is profitable as a monopolist and a duopolist are (B.3) $\quad m_{i}=\Phi_{N}\left(\beta_{i}\right)$ and $d_{i}=\Phi_{N}\left(\beta_{i}-\gamma_{i}\right)$.

The relationship between the reduced-form entry probabilities, and $m_{i}$ and $d_{i}$, $i=1,2$, is given by
(B.4) $\quad \phi_{11}=d_{1} d_{2}$,
(B.5) $\quad \phi_{00}=\left(1-m_{1}\right)\left(1-m_{2}\right)$,
(B.6) $\quad \phi_{10}=m_{1}\left(1-m_{2}\right)+d_{1}\left(m_{2}-d_{2}\right)+\psi\left(m_{1}-d_{1}\right)\left(m_{2}-d_{2}\right)$ $=m_{1}\left(1-d_{2}\right)-(1-\psi)\left(m_{1}-d_{1}\right)\left(m_{2}-d_{2}\right)$,
where $\psi \in[0,1]$. The vector of nonredundant reduced-form parameters is given by $\phi=\left[\phi_{11}, \phi_{00}, \phi_{10}\right]^{\prime}$ and the structural parameters are $\theta=\left[\beta_{1}, \gamma_{1}\right.$, $\left.\beta_{2}, \gamma_{2}\right]^{\prime}$. In addition, there is an auxiliary parameter $\psi$.

## Identified Set

We now provide a characterization of the identified set $\Theta(\phi)$. Define
(B.7) $G(\theta, \alpha)=\left[\begin{array}{l}G_{1}(\theta) \\ G_{2}(\theta)\end{array}\right]-\left[\begin{array}{c}0_{2 \times 1} \\ \alpha\end{array}\right]$,
where

$$
G_{1}(\theta)=\left[\begin{array}{c}
d_{1} d_{2} \\
\left(1-m_{1}\right)\left(1-m_{2}\right)
\end{array}\right], \quad G_{2}(\theta)=m_{1}\left(1-d_{2}\right),
$$

and

$$
\alpha=(1-\psi)\left(m_{1}-d_{1}\right)\left(m_{2}-d_{2}\right)
$$

Moreover, let
(B.8) $\quad \bar{\alpha}(\theta)=\left(m_{1}-d_{1}\right)\left(m_{2}-d_{2}\right)$
and
(B.9) $\quad Q(\theta ; \phi)=\min _{0 \leq \alpha \leq \bar{\alpha}(\theta)}\|\phi-G(\theta, \alpha)\|$.

Notice that by construction, $Q(\theta ; \phi) \geq 0$. In view of (B.4) to (B.6) and (B.7), it is straightforward to verify that the identified set can be characterized as

$$
\theta \in \Theta(\phi) \text { if and only if } Q(\theta ; \phi)=0
$$

Suppose we partition $\theta$ into $\theta=\left[\theta_{1}^{\prime}, \theta_{2}^{\prime}\right]^{\prime}$. Equations (B.4) and (B.5) imply that conditional on $\phi$ and $\theta_{1}$, the subvector $\theta_{2}$ is uniquely determined. Thus, the dimension of the identified set $\Theta(\phi)$ is 2 . Since the entry game is symmetric with respect to firm 1 and firm 2, our illustration focuses on inference for $\theta_{1}$. We denote the identified set for this subvector by $\Theta_{1}(\phi)$ and it can be characterized by the projection

$$
\Theta_{1}(\phi)=\left\{\theta_{1} \mid \exists \theta_{2} \text { s.t. } Q\left(\left[\theta_{1}^{\prime}, \theta_{2}^{\prime}\right]^{\prime} ; \phi\right)=0\right\} .
$$

## Frequentist Inference

The starting point of the frequentist inference is a large-sample approximation of the sampling distribution of $\hat{\phi}_{n}$, defined as

$$
\begin{equation*}
\hat{\phi}_{n}=\left[\frac{n_{11}}{n}, \frac{n_{00}}{n}, \frac{n_{10}}{n}\right]^{\prime}, \tag{B.10}
\end{equation*}
$$

where $n_{11}$ is the number of markets with a duopoly, $n_{00}$ is the number of markets without entry, and $n_{10}$ is the number of markets with a firm 1 monopoly. We assume that
(B.11) $\sqrt{n}\left(\hat{\phi}_{n}-\phi\right) \Longrightarrow N(0, \Lambda(\phi))$
uniformly in $\phi$, where $\Lambda(\phi)$ can be consistently estimated by $\hat{\Lambda}$. Now define

$$
\begin{equation*}
Q_{n}\left(\theta ; \hat{\phi}_{n}\right)=\min _{0 \leq \alpha \leq \bar{\alpha}(\theta)} n\left\|\hat{\phi}_{n}-G(\theta, \alpha)\right\|_{\hat{\Lambda}^{-1}} \tag{B.12}
\end{equation*}
$$

We construct a confidence set for $\theta$ as a level set of $Q_{n}\left(\theta ; \hat{\phi}_{n}\right)$. To do so, we examine the sampling distribution of $Q_{n}\left(\theta ; \hat{\phi}_{n}\right)$ for $\theta \in \Theta(\phi)$.

We partition $\hat{\phi}_{n}$ into $\hat{\phi}_{1, n}$ and $\hat{\phi}_{2, n}$, where the partitions conform with $G_{1}(\theta)$ and $G_{2}(\theta)$. Moreover, define

$$
\hat{H}_{1}(\theta)=\hat{\phi}_{1, n}-G_{1}(\theta), \quad \hat{H}_{2}(\theta)=\hat{\phi}_{2, n}-G_{2}(\theta)
$$

and partition $\hat{\Lambda}$ accordingly. In addition, let

$$
\hat{H}_{2.11}(\theta)=\hat{H}_{2}(\theta)-\hat{\Lambda}_{21} \hat{\Lambda}_{11}^{-1} \hat{H}_{1}(\theta), \quad \hat{\Lambda}_{2.11}=\hat{\Lambda}_{22}-\hat{\Lambda}_{21} \hat{\Lambda}_{11}^{-1} \hat{\Lambda}_{12}
$$

Using the formula for factorizing a joint normal density into a marginal and a conditional density, we can rewrite the objective function as

$$
\begin{equation*}
Q_{n}\left(\theta ; \hat{\phi}_{n}\right)=\min _{0 \leq \alpha \leq \bar{\alpha}(\theta)} n\left(\left\|\hat{H}_{1}(\theta)\right\|_{\hat{\Lambda}_{11}^{-1}}+\left\|\hat{H}_{2.11}(\theta)+\alpha\right\|_{\hat{\Lambda}_{2.11}^{-1}}\right) \tag{B.13}
\end{equation*}
$$

The minimizing value of $\alpha$, which we denote by $\hat{\alpha}(\theta)$, is given by

$$
\hat{\alpha}(\theta)= \begin{cases}0, & \text { if } 0 \leq \hat{H}_{2.11}(\theta)  \tag{B.14}\\ -\hat{H}_{2.11}(\theta), & \text { if }-\bar{\alpha}(\theta) \leq \hat{H}_{2.11}(\theta)<0 \\ \bar{\alpha}(\theta), & \text { otherwise }\end{cases}
$$

In turn, the objective function becomes

$$
Q_{n}\left(\theta ; \hat{\phi}_{n}\right)= \begin{cases}n\left\|\hat{H}_{1}(\theta)\right\|_{\hat{\Lambda}_{11}^{-1}}+n\left\|\hat{H}_{2.11}(\theta)\right\|_{\hat{\Lambda}_{2.11}^{-1}}  \tag{B.15}\\ & \text { if } 0 \leq \hat{H}_{2.11}(\theta) \\ n\left\|\hat{H}_{1}(\theta)\right\|_{\hat{\Lambda}_{11}^{-1}}, & \text { if }-\bar{\alpha}(\theta) \leq \hat{H}_{2.11}(\theta)<0 \\ n\left\|\hat{H}_{1}(\theta)\right\|_{\hat{\Lambda}_{11}^{-1}}+n\left\|\hat{H}_{2.11}(\theta)+\bar{\alpha}(\theta)\right\|_{\hat{\Lambda}_{2.11}^{-1}} \\ \quad \text { otherwise }\end{cases}
$$

As shown in Andrews and Guggenberger (2009), critical values for the construction of uniformly valid confidence sets can be obtained by considering the behavior of the objective function $Q_{n}(\cdot)$ under sequences of parameters. To do so, suppose data are generated based on $\phi_{n}=G\left(\theta_{n}, \alpha_{n}\right)$. To approximate the distribution of $Q_{n}\left(\theta_{n} ; \hat{\phi}_{n}\right)$, notice that

$$
\begin{aligned}
& \hat{H}_{1}\left(\theta_{n}\right)= \\
& \quad \hat{\phi}_{1, n}-G_{1}\left(\theta_{n}\right) \\
& =\hat{\phi}_{1, n}-\phi_{1, n} \\
& \hat{H}_{2.11}\left(\theta_{n}\right)= \\
& \\
& =\hat{\phi}_{2, n}-G_{2}\left(\theta_{n}\right)-\hat{\Lambda}_{21} \hat{\Lambda}_{11}^{-1}\left[\hat{\phi}_{1, n}-G_{1}\left(\theta_{n}\right)\right] \\
&
\end{aligned}
$$

Let

$$
\begin{aligned}
& Z_{1, n}=\sqrt{n} \hat{\Lambda}_{11}^{-1 / 2}\left(\hat{\phi}_{1, n}-\phi_{1, n}\right) \\
& Z_{2.11, n}=\sqrt{n} \hat{\Lambda}_{2.11}^{-1 / 2}\left[\hat{\phi}_{2, n}-\phi_{2, n}-\hat{\Lambda}_{21} \hat{\Lambda}_{11}^{-1}\left(\hat{\phi}_{1, n}-\phi_{1, n}\right)\right] .
\end{aligned}
$$

Using this notation, we can rewrite the objective function as

$$
Q_{n}\left(\theta_{n} ; \hat{\phi}_{n}\right)=\left\{\begin{array}{c}
\left\|Z_{1, n}\right\|+\left\|Z_{2.11, n}-\sqrt{n} \hat{\Lambda}_{2.11}^{-1 / 2} \alpha_{n}\right\|  \tag{B.16}\\
\quad \text { if } \sqrt{n} \hat{\Lambda}_{2.11}^{-1 / 2} \alpha_{n} \leq Z_{2.11, n} \\
\left\|Z_{1, n}\right\|+\left\|Z_{2.11, n}+\sqrt{n} \hat{\Lambda}_{2.11}^{-1 / 2}\left(\bar{\alpha}\left(\theta_{n}\right)-\alpha_{n}\right)\right\| \\
\quad \text { if } Z_{2.11, n}<-\sqrt{n} \hat{\Lambda}_{2.11}^{-1 / 2}\left(\bar{\alpha}\left(\theta_{n}\right)-\alpha_{n}\right) \\
\left\|Z_{1, n}\right\|, \quad \text { otherwise }
\end{array}\right.
$$

Now suppose that $\sqrt{n} \Lambda_{2.11}^{-1 / 2} \alpha_{n} \longrightarrow a$ and $\sqrt{n} \Lambda_{2.11}^{-1 / 2}\left(\bar{\alpha}\left(\theta_{n}\right)-\alpha_{n}\right) \longrightarrow \bar{a}$, where $a \in \mathbb{R}^{+} \cup \infty$ and $\bar{a} \in \mathbb{R}^{+} \cup \infty$. Thus,

$$
Q_{n}\left(\theta_{n} ; \hat{\phi}_{n}\right) \Longrightarrow \begin{cases}\left\|Z_{1}\right\|+\left\|Z_{2.11}-a\right\|, & \text { if } a \leq Z_{2.11},  \tag{B.17}\\ \left\|Z_{1}\right\|+\left\|Z_{2.11}+\bar{a}\right\|, & \text { if } Z_{2.11}<-\bar{a} \\ \left\|Z_{1}\right\|, & \text { otherwise }\end{cases}
$$

where $Z_{1} \sim N\left(0, I_{2}\right), Z_{2.11} \sim N(0,1)$, and $Z_{1}$ and $Z_{2.11}$ are independent. We have to distinguish three cases. First,

$$
\begin{aligned}
Q_{n}\left(\theta_{n} ; \hat{\phi}_{n}\right) & \Longrightarrow\left\|Z_{1}\right\| \\
& \leq\left\|Z_{1}\right\|+\left\|Z_{2.11}\right\| I\left\{Z_{2.11} \geq 0\right\} \quad \text { if } \quad a=\infty, \bar{a}=\infty
\end{aligned}
$$

Second,

$$
\begin{aligned}
Q_{n}\left(\theta_{n} ; \hat{\phi}_{n}\right) & \Longrightarrow\left\|Z_{1}\right\|+\left\|Z_{2.11}-a\right\| I\left\{Z_{2.11} \geq a\right\} \\
& \leq\left\|Z_{1}\right\|+\left\|Z_{2.11}\right\| I\left\{Z_{2.11} \geq 0\right\} \quad \text { if } \quad a<\infty, \bar{a}=\infty
\end{aligned}
$$

Third,

$$
\begin{aligned}
Q_{n}\left(\theta_{n} ; \hat{\phi}_{n}\right) \Longrightarrow & \left\|Z_{1}\right\|+\left\|Z_{2.11}-a\right\| I\left\{Z_{2.11} \geq a\right\} \\
& +\left\|Z_{2.11}+\bar{a}\right\| I\left\{Z_{2.11}<-\bar{a}\right\} \quad \text { if } \quad a<\infty, \bar{a}<\infty \\
\leq & \left\|Z_{1}\right\|+\left\|Z_{2.11}\right\| .
\end{aligned}
$$

The bound for this last case is weaker than the bounds for the first two cases. The case $\bar{a}<0$ arises only if $\bar{\alpha}\left(\theta_{n}\right) \longrightarrow 0$ sufficiently fast, meaning that $\theta_{n}$ approaches an area of the parameter space in which the model is point-identified. From the definition of $\bar{\alpha}(\theta)$ in (B.8), it follows that the third case arises if one of the interaction parameters is close to 0 . In our numerical illustration, we use a conservative fixed critical value obtained from the $1-\tau$ quantile of a $\chi^{2}$ $(\mathrm{df}=3)$.

A frequentist confidence set for the four-dimensional parameter vector $\theta$ can then be defined as the level set

$$
\begin{equation*}
\mathrm{CS}_{F}^{\theta}\left(Y^{n}\right)=\left\{\theta \mid Q_{n}\left(\theta ; \hat{\phi}_{n}\right) \leq c_{\tau}^{2}\right\} \tag{B.18}
\end{equation*}
$$

We are restricting our attention to confidence sets constructed from fixed (rather than sample-size and $\theta$-dependent) critical values. In principle, one can construct the set $\mathrm{CS}_{F}^{\theta}\left(Y^{n}\right)$ by evaluating the objective function $Q_{n}\left(\theta ; \hat{\phi}_{n}\right)$ on a four-dimensional grid. However, since the identified set $\Theta(\phi)$ lies in a twodimensional subspace, the specification of a suitable grid is difficult. Moreover, our goal is to construct a confidence set for the subvector $\theta_{1}$. Thus, we let

$$
\underline{Q}_{n}\left(\theta_{1} ; \hat{\phi}_{n}\right)=\min _{\theta_{2}} Q_{n}\left(\left[\theta_{1}^{\prime}, \theta_{2}\right]^{\prime} ; \hat{\phi}_{n}\right)
$$

and define

$$
\begin{equation*}
\operatorname{CS}_{F}^{\theta_{1}}\left(Y^{n}\right)=\left\{\theta \mid \underline{Q_{n}}\left(\theta_{1} ; \hat{\phi}_{n}\right) \leq c_{\tau}^{2}\right\} \tag{B.19}
\end{equation*}
$$

The confidence set $\mathrm{CS}_{F}^{\theta_{1}}\left(Y^{n}\right)$ is the projection of $\mathrm{CS}_{F}^{\theta}\left(Y^{n}\right)$ onto the domain of $\theta_{1}$. To compute the projection-based confidence set, we specify a twodimensional grid for $\theta_{1}$ and evaluate the objective function $\underline{Q}_{n}\left(\theta_{1} ; \hat{\phi}_{n}\right)$ for each grid point. A parameter value is included in the confidence set if $\underline{Q}_{n}\left(\theta_{1} ; \hat{\phi}_{n}\right) \leq$ $c_{\tau}^{2}$.

## Bayesian Inference: Draws From the Conditional Prior

Prior 1 and prior 2 are specified on the $\theta-\psi$ space through densities $p(\theta, \psi)$. These priors induce a prior distribution on the reduced-form parameters $\phi$. As explained in the main text, the conditional prior of $\theta$ given $\phi$ will not get updated through the likelihood function and the posterior will converge to $p\left(\theta \mid \hat{\phi}_{n}\right)$. To characterize the conditional prior $p\left(\theta_{1} \mid \phi\right)$, we conduct the following change of variables. Let

$$
\begin{equation*}
Z=\left[\beta_{1}, \gamma_{1}, \beta_{2}, \gamma_{2}, \psi\right]^{\prime} \tag{B.20}
\end{equation*}
$$

and
(B.21) $\quad X=\left[\beta_{1}, \gamma_{1}, \phi_{11}, \phi_{00}, \phi_{10}\right]^{\prime}$.

To convert a prior density for $Z=f(X)$ into a prior for $X$, we can use

$$
\begin{equation*}
p_{X}(X)=p_{Z}(f(X))\left|f^{\prime}(X)\right| \tag{B.22}
\end{equation*}
$$

Once we have derived $p_{X}(X)$, we can proceed as follows. Notice that

$$
\begin{equation*}
p\left(\theta_{1} \mid \phi\right) \propto p\left(\theta_{1}, \phi\right) \tag{B.23}
\end{equation*}
$$

We use a random-walk Metropolis algorithm to generate draws from $p\left(\theta_{1} \mid \phi\right)$. For this algorithm, it is sufficient to be able evaluate the joint density $p\left(\theta_{1}, \phi\right)$ numerically. Descriptions of the algorithm can be found in many textbooks (e.g., Geweke (2005)). Our proposal density is multivariate Gaussian with a covariance matrix that equals a suitably scaled identity matrix.

We proceed by characterizing the function $f(X)$ component by component and then derive the Jacobian $f^{\prime}(X)$. The following functional relationships are useful:

$$
\begin{aligned}
& m_{1}=\Phi_{N}\left(\beta_{1}\right), \quad m_{2}=\Phi_{N}\left(\beta_{2}\right) \\
& d_{1}=\Phi_{N}\left(\beta_{1}-\gamma_{1}\right), \quad d_{2}=\Phi_{N}\left(\beta_{2}-\gamma_{2}\right)
\end{aligned}
$$

Since we have to solve for $\beta_{2}$ and $\gamma_{2}$, notice that

$$
\beta_{2}=\Phi_{N}^{-1}\left(m_{2}\right), \quad \gamma_{2}=\Phi_{N}^{-1}\left(m_{2}\right)-\Phi_{N}^{-1}\left(d_{2}\right)
$$

The Nash equilibrium conditions imply that

$$
\begin{aligned}
& \phi_{00}=\left(1-m_{1}\right)\left(1-m_{2}\right), \\
& \phi_{11}=d_{1} d_{2}, \\
& \phi_{10}=m_{1}\left(1-m_{2}\right)+d_{1}\left(m_{2}-d_{2}\right)+\psi\left(m_{1}-d_{1}\right)\left(m_{2}-d_{2}\right) .
\end{aligned}
$$

We can use these conditions to solve for $m_{2}, d_{2}$, and $\psi$ :

$$
\begin{aligned}
& m_{2}=1-\frac{\phi_{00}}{1-m_{1}}, \\
& d_{2}=\frac{\phi_{11}}{d_{1}} \\
& \psi=\frac{\phi_{10}-m_{1}\left(1-m_{2}\right)-d_{1}\left(m_{2}-d_{2}\right)}{\left(m_{1}-d_{1}\right)\left(m_{2}-d_{2}\right)} .
\end{aligned}
$$

The expression for $\psi$ can be simplified by replacing $m_{2}$ and $d_{2}$,

$$
\begin{aligned}
\psi & =\frac{\phi_{10}-m_{1}\left(1-m_{2}\right)-d_{1}\left(m_{2}-d_{2}\right)}{\left(m_{1}-d_{1}\right)\left(m_{2}-d_{2}\right)} \\
& =\frac{\phi_{10}-\phi_{00} \frac{m_{1}}{1-m_{1}}-d_{1}\left(1-\frac{\phi_{00}}{1-m_{1}}-\frac{\phi_{11}}{d_{1}}\right)}{\left(m_{1}-d_{1}\right)\left(1-\frac{\phi_{00}}{1-m_{1}}-\frac{\phi_{11}}{d_{1}}\right)} \\
& =\frac{\phi_{10}\left(1-m_{1}\right)-\phi_{00} m_{1}-d_{1}\left(1-m_{1}-\phi_{00}-\frac{\phi_{11}\left(1-m_{1}\right)}{d_{1}}\right)}{\left(m_{1}-d_{1}\right)\left(1-m_{1}-\phi_{00}-\frac{\phi_{11}\left(1-m_{1}\right)}{d_{1}}\right)} \\
& =\frac{\phi_{10}\left(1-m_{1}\right)-\phi_{00} m_{1}-d_{1} g(X)}{\left(m_{1}-d_{1}\right) g(X)}
\end{aligned}
$$

where

$$
g(X)=\left(1-m_{1}-\phi_{00}-\frac{\phi_{11}\left(1-m_{1}\right)}{d_{1}}\right)
$$

Combining terms, we obtain the following expressions for the components of $f(X)$ :

$$
f_{1}(X)=\beta_{1}
$$

$$
\begin{aligned}
f_{2}(X) & =\gamma_{1} \\
f_{3}(X) & =\Phi_{N}^{-1}\left(1-\frac{\phi_{00}}{1-\Phi_{N}\left(\beta_{1}\right)}\right) \\
f_{4}(X) & =f_{3}(X)-\Phi_{N}^{-1}\left(\frac{\phi_{11}}{\Phi_{N}\left(\beta_{1}-\gamma_{1}\right)}\right) \\
f_{5}(X) & =\frac{A(X)}{B(X)} \\
& =\frac{\phi_{10}\left(1-\Phi_{N}\left(\beta_{1}\right)\right)-\phi_{00} \Phi_{N}\left(\beta_{1}\right)-\Phi_{N}\left(\beta_{1}-\gamma_{1}\right) g(X)}{\left(\Phi_{N}\left(\beta_{1}\right)-\Phi_{N}\left(\beta_{1}-\gamma_{1}\right)\right) g(X)}
\end{aligned}
$$

where

$$
g(X)=\left(1-\Phi_{N}\left(\beta_{1}\right)-\phi_{00}-\frac{\phi_{11}\left(1-\Phi_{N}\left(\beta_{1}\right)\right)}{\Phi_{N}\left(\beta_{1}-\gamma_{1}\right)}\right)
$$

Now we can calculate the derivatives for the Jacobian matrix. For this, define

$$
\psi(z)=\frac{\partial \Phi_{N}^{-1}(z)}{\partial z}=\frac{1}{\phi_{N}\left(\Phi_{N}^{-1}(z)\right)}
$$

Term $f_{1}(X)$ :

$$
\frac{\partial f_{1}(X)}{\partial \beta_{1}}=1
$$

Term $f_{2}(X)$ :

$$
\frac{\partial f_{2}(X)}{\partial \gamma_{1}}=1
$$

Term $f_{3}(X)$ :

$$
\begin{aligned}
& \frac{\partial f_{3}(X)}{\partial \beta_{1}}=-\psi\left(1-\frac{\phi_{00}}{1-\Phi_{N}\left(\beta_{1}\right)}\right) \frac{\phi_{00}}{\left[1-\Phi_{N}\left(\beta_{1}\right)\right]^{2}} \phi_{N}\left(\beta_{1}\right), \\
& \frac{\partial f_{3}(X)}{\partial \phi_{00}}=-\psi\left(1-\frac{\phi_{00}}{1-\Phi_{N}\left(\beta_{1}\right)}\right) \frac{1}{1-\Phi_{N}\left(\beta_{1}\right)}
\end{aligned}
$$

Term $f_{4}(X)$ :

$$
\begin{aligned}
& \frac{\partial f_{4}(X)}{\partial \beta_{1}}=\frac{\partial f_{3}(X)}{\partial \beta_{1}}+\psi\left(\frac{\phi_{11}}{\Phi_{N}\left(\beta_{1}-\gamma_{1}\right)}\right) \frac{\phi_{11} \phi_{N}\left(\beta_{1}-\gamma_{1}\right)}{\Phi_{N}^{2}\left(\beta_{1}-\gamma_{1}\right)} \\
& \frac{\partial f_{4}(X)}{\partial \gamma_{1}}=-\psi\left(\frac{\phi_{11}}{\Phi_{N}\left(\beta_{1}-\gamma_{1}\right)}\right) \frac{\phi_{11} \phi_{N}\left(\beta_{1}-\gamma_{1}\right)}{\Phi_{N}^{2}\left(\beta_{1}-\gamma_{1}\right)}
\end{aligned}
$$

$$
\begin{aligned}
& \frac{\partial f_{4}(X)}{\partial \phi_{11}}=-\psi\left(\frac{\phi_{11}}{\Phi_{N}\left(\beta_{1}-\gamma_{1}\right)}\right) \frac{1}{\Phi_{N}\left(\beta_{1}-\gamma_{1}\right)} \\
& \frac{\partial f_{4}(X)}{\partial \phi_{00}}=\frac{\partial f_{3}(X)}{\partial \phi_{00}}
\end{aligned}
$$

$\operatorname{Term} f_{5}(X)$ :

$$
\frac{\partial f_{5}(X)}{\partial x}=\frac{\frac{\partial A(X)}{\partial x} B(X)-A(X) \frac{\partial B(X)}{\partial x}}{B(X)^{2}}
$$

Term $A(X)$ :

$$
\begin{aligned}
\frac{\partial A(X)}{\partial \beta_{1}}= & -\left(\phi_{10}+\phi_{00}\right) \phi_{N}\left(\beta_{1}\right)-\phi_{N}\left(\beta_{1}-\gamma_{1}\right) g(X) \\

\end{aligned}
$$

Term $g(X)$ :

$$
\begin{aligned}
& \frac{\partial g(X)}{\partial \beta_{1}}=-\phi_{N}\left(\beta_{1}\right)+\frac{\phi_{11} \phi_{N}\left(\beta_{1}\right)}{\Phi_{N}\left(\beta_{1}-\gamma_{1}\right)}+\frac{\phi_{11}\left(1-\Phi_{N}\left(\beta_{1}\right)\right) \phi_{N}\left(\beta_{1}-\gamma_{1}\right)}{\Phi_{N}^{2}\left(\beta_{1}-\gamma_{1}\right)} \\
& \frac{\partial g(X)}{\partial \gamma_{1}}=-\frac{\phi_{11}\left(1-\Phi_{N}\left(\beta_{1}\right)\right) \phi_{N}\left(\beta_{1}-\gamma_{1}\right)}{\Phi_{N}^{2}\left(\beta_{1}-\gamma_{1}\right)} \\
& \frac{\partial g(X)}{\partial \phi_{11}}=-\frac{1-\Phi_{N}\left(\beta_{1}\right)}{\Phi_{N}\left(\beta_{1}-\gamma_{1}\right)} \\
& \frac{\partial g(X)}{\partial \phi_{00}}=-1
\end{aligned}
$$

Bayesian Inference: Draws From the Posterior
According to Equations (B.3)-(B.6), we can express the reduced-form probabilities as functions of $\theta$ and $\psi$. Thus, the likelihood function is given by

$$
\begin{equation*}
p\left(Y^{n} \mid \theta, \psi\right)=\phi_{11}^{n_{11}}(\theta, \psi) \phi_{00}^{n_{00}}(\theta, \psi) \phi_{10}^{n_{10}}(\theta, \psi) \phi_{01}^{n_{01}}(\theta, \psi) \tag{B.24}
\end{equation*}
$$

If this prior distribution is combined with a prior specified on the $\theta-\psi$ space, then the posterior is given by

$$
\begin{equation*}
p\left(\theta, \psi \mid Y^{n}\right) \propto p\left(Y^{n} \mid \theta, \psi\right) p(\theta, \psi) \tag{B.25}
\end{equation*}
$$

and draws can be generated with a random-walk Metropolis algorithm.
In addition to priors 1 and 2, we consider a prior that is flat with respect to the reduced-form parameters. Conditional on $\phi$, the prior for $\theta_{1}$ is uniform on the identified set $\Theta_{1}(\phi)$. To obtain draws from the posterior distribution of $\theta_{1}$, we sample (i) from $p\left(\phi \mid Y^{n}\right)$ and (ii) from $p\left(\theta_{1} \mid \phi\right)$. For step (i), notice that under the flat prior for $\phi$, the posterior distribution $P_{Y^{n}}^{\phi}$ takes the form of a Dirichlet distribution

$$
\left[\phi_{11}, \phi_{00}, \phi_{10}, \phi_{01}\right]^{\prime} \sim \operatorname{Dirichlet}\left(n_{11}+1, n_{00}+1, n_{10}+1, n_{01}\right)
$$

A draw from this Dirichlet distribution can be generated as follows: Let $a_{j} \sim \mathcal{G}\left(n_{j}+1,1\right)$, where $j \in\{11,00,10,01\}$, and $\mathcal{G}(\alpha, 1)$ denotes a Gamma distribution with shape parameter $\alpha$ and scale parameter 1 . Then set

$$
\phi=\left[a_{11}, a_{00}, a_{10}, a_{01}\right]^{\prime} /\left(a_{11}+a_{00}+a_{10}+a_{01}\right) .
$$

For step (ii) we specify a two-dimensional grid for $\theta_{1}$ so as to construct projections of the identified set $\Theta_{1}(\phi)$ onto the $\beta_{1}$ and $\gamma_{1}$ ordinates. Let these projections be delimited by $\underline{\beta}_{1}, \bar{\beta}_{1}, \underline{\gamma}_{1}$, and $\bar{\gamma}_{1}$. We then use an acceptance sampler with a proposal density that is uniform on $\left[\underline{\beta}_{1}, \bar{\beta}_{1}\right] \otimes\left[\underline{\gamma}_{1}, \bar{\gamma}_{1}\right]$ to obtain a draw of $\theta_{1}$ conditional on $\phi$.

## Bayesian Inference: Credible Sets

Credible sets are computed according to the following steps:
Step 1. Construct two independent sequences $\left\{\theta_{1, s}^{(1)}\right\}_{s=1}^{S}$ and $\left\{\theta_{1, s}^{(2)}\right\}_{s=1}^{S}$ of draws from the distribution of $\theta_{1}$.

Step 2. Use the $\left\{\theta_{1, s}^{(1)}\right\}_{s=1}^{S}$ draws to construct kernel density estimates $\hat{p}\left(\theta_{1, s}^{(2)}\right)$ for each $\theta_{1, s}^{(2)}, s=1, \ldots, S$.

Step 3. Find a cutoff $\kappa$ such that $(1-\tau) S$ of the density estimates $\hat{p}\left(\theta_{1, s}^{(2)}\right)$ are greater than or equal to $\kappa$.

Step 4. Use the $\left\{\theta_{1, s}^{(1)}\right\}_{s=1}^{S}$ draws to construct kernel density estimates $\hat{p}\left(\theta_{1}\right)$ for values of $\theta_{1}$ on a two-dimensional grid. Include a particular grid point into the credible set if $\hat{p}\left(\theta_{1}\right) \geq \kappa$.
