APPENDIX A: NONIDENTIFICATION OF DOSAGE EFFECT

Consider a standard potential outcomes model in which there are three possible “dosages” of SYEP participation: $p = 0, 1, 2$ for 0, 1, or 2 times participating, respectively.¹ Potential outcomes for each state p are given by

$$Y_p = \delta_p + U_p, \quad (1)$$

where by normalization $E(U_p) = 0$ for all p . The average effect of participating in SYEP once (relative to never participating) is given by $\delta_1 - \delta_0$, and the average effect of participating twice (versus once) is given by $\delta_2 - \delta_1$.

We define a *Dosage Effect* as

$$DE_{21} = (Y_2 - Y_1) - (Y_1 - Y_0)$$

and, therefore, the average dosage effect is $ADE_{21} = (\delta_2 - \delta_1) - (\delta_1 - \delta_0)$. We are interested in testing the whether $ADE_{21} = 0$. Rejecting this restriction with a positive (negative) ADE_{21} would be evidence of supermodularity (submodularity) in SYEP participation: Students who participate twice enjoy a larger (smaller) effect of the second participation.

Amy Ellen Schwartz: amyschwartz@maxwell.syr.edu

Jacob Leos-Urbel: jleos@tippingpoint.org

Joel McMurry: mcmurry2@wisc.edu

Matthew Wiswall: mjwiswall@wisc.edu

¹Although we do consider three-time applicants in the main analyses, here we restrict our attention to participating at most twice. The point at hand is made no clearer by considering higher “dosages.”

Next, consider attempting to identify ADE_{21} using the data generated by SYEP. For simplicity, we assume full compliance (winning the lottery implies participation). Let $W_p = 1$ denote winning the p^{th} lottery and 0 otherwise, and let $A_p = 1$ denote applying to the p^{th} lottery with 0 otherwise. We can identify at least two local effects with the following estimands:

$$\beta_1 = E(Y | W_1 = 1, A_1 = 1) - E(Y | W_1 = 0, A_1 = 1), \quad (2)$$

$$\beta_2 = E(Y | W_2 = 1, W_1 = 1, A_2 = 1, A_1 = 1) - E(Y | W_2 = 0, W_1 = 1, A_2 = 1, A_1 = 1). \quad (3)$$

As seen below, β_1 and β_2 correspond to the average treatment effects of the first and second lottery for Groups 1 and 2, respectively, defined in the main text (see equation (5)). Group 1 of first time appliers who have never participated and Group 2 who apply twice after having won and participated once.

β_2 may be written as

$$\begin{aligned} \beta_2 &= E(Y_2 | W_2 = 1, W_1 = 1, A_2 = 1, A_1 = 1) - E(Y_1 | W_2 = 0, W_1 = 1, A_2 = 1, A_1 = 1) \\ &= \delta_2 + E(U_2 | W_2 = 1, W_1 = 1, A_2 = 1, A_1 = 1) \\ &\quad - \{ \delta_1 + E(U_1 | W_2 = 0, W_1 = 1, A_2 = 1, A_1 = 1) \} \\ &= (\delta_2 - \delta_1) + E(U_2 - U_1 | W_1 = 1, A_2 = 1, A_1 = 1), \end{aligned}$$

where the last equality is given by lottery randomization, which implies that $E(U_p | W_p = 1, \cdot) = E(U_p | W_p = 0, \cdot)$ for all p (and conditioning variables prior to p). Therefore, β_2 does indeed identify the average treatment effect of winning the second lottery for Group 2. $(\delta_2 - \delta_1)$ is the average effect of participating twice relative to once, and $E(U_2 - U_1 | W_1 = 1, A_2 = 1, A_1 = 1)$ is the selection effect for Group 2, who apply twice after having won and participated once.

In general, the application decision is likely endogenous, and so

$$E(U_2 - U_1 | W_1 = 1, A_2 = 1, A_1 = 1) \neq E(U_2 - U_1) = 0.$$

Therefore, comparing the outcomes of the second lottery winners and losers in Group 2 does not identify the average effect of participating twice over once. Further, we see from decomposing β_1 that

$$\beta_1 = (\delta_1 - \delta_0) + E(U_1 - U_0 | A_1 = 1).$$

The difference in these two estimands identifies

$$\begin{aligned} \beta_2 - \beta_1 &= (\delta_2 - \delta_1) - (\delta_1 - \delta_0) + E(U_2 - U_1 | W_1 = 1, A_2 = 1, A_1 = 1) \\ &\quad - E(U_1 - U_0 | A_1 = 1). \end{aligned}$$

And it is clear that assuming that the selection terms are equal in magnitude is extremely stringent and unlikely to obtain. We conclude that the average dosage effect is not identified.

APPENDIX B: ADDITIONAL TABLES

TABLE B.1. Lottery randomization results by covariate.

	Win Coef	SE

TABLE B.12. Joint test of zero treatment effect on outcomes 1–6.

	Full Sample	Group 1	Group 2	Group 3
F-Stat	2.731	1.322	2.511	1.102
P-Value	0.012	0.243	0.020	0.359

Note: For each group, statistics generated from F-test of joint restriction that treatment effect is zero for all outcomes other than average Z-score. Average Z-score is omitted as students who attempt no exams have no defined average score. Group 1 consists of all first-time applicants in years 2006–2008. Group 2 is all students who applied for the second time in 2006–2008 and had applied, won, and participated in the prior year. Group 3 is all students who applied for the third time in 2006–2008 and had applied, won, and participated in each of the two years prior. Full Sample is identical to that analyzed in Tables 6–7.

Co-editor Peter Arcidiacono handled this manuscript.
